

The three ruptures side by side: mostly the same bureaucracy

In each panel the left column is the rank held on the eve of the rupture and the right column the rank of the next post taken within three years, for the people who took one. The diagrams resemble each other because most of what they show is the standing mobility of the Tunisian administration rather than the rupture: across the whole matrix the three differ from one another by 5.6 to 6.5 points on average, and each from its own era's ordinary times by 3.1 to 7.0. Only 2021 departs from its own era - 44% of its senior tier reappears at head of service or below, against 33% in ordinary times, where 1987 and 2011 both fall slightly short of theirs.

Source: Journal Officiel de la République Tunisienne, 1957–2026 (6,378 French issues, jort.tn). Author's extraction. Each panel is scaled to its own total, so a node's height is the share of that cohort's movers, not a count: the cohorts run from 1,179 to 4,050 and a common scale would compare nothing. Node figures are people. Rank is the ordinal scale in the codebook, a person holding several posts placed at the highest. Only people observed in a post before and after appear, which is a tenth or so of each cohort; the rest have no further post in the record, and the gazette's patchy treatment of departures makes that unreadable as removal from the state. Falls here cross a tier boundary, a higher bar than the any-rank-fall measure in the demotion figure.
