

The core, and the same core wired at random

Elite families here marry widely rather than into circles. The observed core closes only 1.2x as many triangles as a random graph giving every family the same number of allies, and scores $z=+1.9$ on modularity against it — inside the noise of the null itself. Both panels run the same layout at the same settings, so any difference in how clumped they look is a difference in the graphs. Measured by tools/audit_alliances.py.

Source: rodovid.org genealogies, filtered to Tunisian families by tools/build_rodovid_elites.py, collapsed to families by tools/build_family_alliances.py. Surnames are rodovid's own reduction of the name, so patronymic nodes (Ali, Mahmoud, Youssef) aggregate unrelated people. The export is truncated at 65,535 rows: every count here is a floor. 236 families and 1048 alliances in each panel.
