

After a rupture the interior keeps more of its own

People holding a post in the interior apparatus — the ministry with the governorates and municipalities — on the eve of each rupture, by where their next post within five years sits. All three ruptures point the same way, and 2011 and 2021 clear their interval; 1987's +1.9 points does not. The larger movement is not the ruptures at all: in ordinary times retention runs 52% to 56% to 66% across the three eras, so the apparatus was closing in on itself anyway. Where the leavers go barely moves — of the 21 destination comparisons on the right, 8 clear their own interval, and 3 of those are the bucket of bodies the record will not place.

Source: Journal Officiel de la République Tunisienne, 1957–2026 (6,378 French issues, jort.tn). Author's extraction. The cohort is the same as in the interior flow figure: people in an interior-apparatus post on the eve of the rupture who take another post within five years, a person holding several posts placed at the highest. Retention is a share of that cohort; the destination blocs are shares of the leavers alone, so that the two panels do not show the same fact twice. Intervals are Wilson, which unlike the normal approximation does not run below zero on the small shares here. Destination is read from the body's portfolio where it has one and from its name where it does not; the spell's own parent field is not used, being assigned from the surrounding act and demonstrably wrong where one decree appoints across several ministries. What remains unattributable is shown rather than dropped, and it is why the 1987 row of the right-hand panel should not be read closely: that rupture sends 92 people out of the apparatus in five years, a third of them to bodies the record does not let us place.
